Is there any function I can use to do this? What about Bradford Score? then, if it is possible to create a login sheet that directly displays the presence on another sheet for the current date of a specific employee. For example, sheet 7 (total call) would have Joe 5 (where 5 is the result of the formula I am looking for to count every time "Joe" appears on sheets 1-6). What I want to do is go to the worksheet that has the largest number of rows (it's always the same worksheet, so I know which one it is), set the zoom factor for THAT worksheet (which I can do, and it always has the same number of rows), and then take THAT zoom factor, whatever it is – and it will vary depending on the user – and apply this to the other worksheets that have a similar layout. Days Sun Mon Tue Date 1 2 3 4 1 John P A A P 2 Lucia A P P A 3 Now I want to calculate the total Sundays, Mondays, Tuesdays etc. Code:Sheets ("WELCOME").Select Range ("A1:N18").Select ActiveWindow.Zoom = True By repeating this code for each worksheet, I can make each worksheet zoom in exactly the right way. On sheet 7 I want to have a cell next to the name of each person that counts the number of times their name appeared on the other 6 sheets. Currently, I can make it show the contents of individual cells from Sheet 1 in Sheet 2 using this formula in the formula bar for each cell in Sheet 2: =Sheet1!A3 (or any cell whatsoever) All right, but I would just like to have a formula that will reproduce the entire column (ie. For example: Columns A and B of sheet 1 are linked to columns A and B of sheet 2. On sheet 1 you will find my formula. That is, there are 25 employees working in a particular corporate sector. Working with Workforce Planning expert Dr. Tony Miller, I created a Bradford score sheet that mugla mugla met m©AugIA 7oEÁN .drofdarB ofEªÁÁautnop airpªÁRp aus eirc ofEªÁÁazinagro reuqlauq e aossep reuqlauq euq Is this possible? \ Sometimes, it takes 45 seconds to calculate the entire sheet, other times it takes 5 minutes. All horns are in order, then the column A looks like: 01/01/2007 01/02/2007 01/03/2007 I have data from 2007 to 2010. Thanks in advance for any advice. If I add a new line to the column in the spreadsheet 1, I would also like it to be automatically updated in the spreadsheet 2. Any idea would be greatly appreciated! Thank you very much, Caitlin Hi- I'm brand new for Mr. Excel and would love some advice. Does anyone know how to do this? Hello everyone. So I'm so hopeful I'm worried about making a schedule for my school that we used to do manually I need a code to distribute the schedule of each teacher with the following basis: the number of classes Professor is assigned to work with , multiplied by the number of perch (which is alterable). In a Cula Lula, I want him to look at sheet 2 column B and look for instances of "A", so I want him to look at the same line that he found "A" and look at the value in the column "N" and evaluate whether there is an amount. I need to look for data from a calama in an Excel worksheet, compare them to a list on a second spreadsheet and when they are the same, pick up a different column in the second spreadsheet and release it back on the first spreadsheet. If I am simply trying to fill a combination box in a user form of a range named in a spreadsheet, I want to fill the combination box as soon as the user form start. What I'm trying is the following fan in Lula E2 from Leaf 2: = Index ('Worksheet 1'! A: A, Match (C2, 'Worksheet 1'! E: E, 0), 5) But all What I get is no results "Name" "Date" hours "The 8th leaf consists of" name ", " days of the week in your own column (7 columns in total) ", " total hours "and" total days worked "now ... I set up an automatic run macro that automatically sets the zoom factor for better adjustment, for several several Worksheets, and this works well. The sheet is configured with winning dates in column A, days overdue in column B and Date completed in column C. I am trying to get counts from certain values. Code: sub button1_click () set userform1.combobox1.list = sheets (á € œsheets (á € œsheet1á €) .Range (á € œMyRangeá €) UserForm1.Show End Sub I am very new to VBA, so please Sorry My ignorance, any help would be greatly appreciated concerns Jim and this code will work? Every day is always a different group and what I'm expecting is to create one that can pick up every name with your hours and play them on the 8th leaf. Is there a way to calculate the days of days between a dates column? The most accurate method of doing this used to be using Bradford's Formula. We have improved this and turn the results by creating our 0 -100 reliability range: the same linear scale used for competence and performance. Basically, I have a spreadsheet that contains a table of entries, and each entry receives a date stamp in the first column. This file is to track about 100 employees that are in a rotating work schedule. Here is the code that does this. Edit: I'm using Excel 2007 w / Windows XP This is probably an easy question for most of you, but it's killing me. I need a formula that counts missing days from one once as a period. Based on this and based on the best practices, you can then decide the cutting points for Scientific and Simple: Bradford Score is a very powerful tool in this modern world of playing diseases and duvet days . This was how an automated service sheet has created with Name Login. Thanks in advance for your help. But HR or timekeeper does not know who is present and absent. But I'm not sure how to take into account lunch pause (see attached sheet).
